BACKGROUND

- In 2016, 18,489 cases of buttock augmentation with fat grafting (BFG) were performed by members of the American Society of Plastic Surgeons (ASPS); an increase of 26% from 2015.1
- Commonly performed in outpatients, concerns have arisen over case reports of death in association with BFG.
- A 2017 report from the Aesthetic Surgery Education and Research Foundation Task Force found that, of 198,857 reported BFG cases, there were 32 fatalities from pulmonary fat emboli and 103 occurrences of non-fatal fat emboli.2 However, there is limited demographic detail provided.
- The present study aims to identify deaths associated with BFG, in the first detailed analysis of the American Association for Accreditation of the Ambulatory Surgery Facilities’ (AAAASF) patient database.

METHODS

- AAAASF is a national accrediting organization for outpatient surgical facilities, requiring participants to provide annual data on surgical complications and sample elective patients.
- Retrospective analysis of the AAAASF patient database was performed between 2001-2015.
- Patients who died undergoing BFG were identified with procedural and complication codes.

ACKNOWLEDGEMENTS

Thank you to AAAASF for providing access to their patient database.

CONCLUSION

- There is growing concern over mortality occurring in association with BFG. A retrospective study in Mexico and Colombia found that there were 22 deaths attributed to BFG. Of these, fifteen occurred at the time of lipoinjection, while eight occurred post-operatively, but within 24 hours. Moreover, in 21 of these cases, the cause of death was fat embolism, as determined by autopsy.3
- The present study provides further detail on five cases of BFG-associated mortality and interestingly, none were definitely due to fat embolus.
- Accrediting agencies provide a useful source of information on morbidity and mortality in association with outpatient plastic surgery procedures.

Here we describe five deaths occurring in the United States after buttock fat grafting; none were attributed to fat embolus. Further research is needed to understand the causative mechanisms underlying death in these cases.
